【Class 1】 Gain Adjustments

Pr1.00	Label	1 st position loop gain			Mode	P		
	Range	0~3000 0	Unit	0.1/s	Default	320	Index	2100h
	Activation	Immediate						
<p>Higher position loop gain value improves the responsiveness of the servo driver and lessens the positioning time.</p> <p>Position loop gain value shouldn't exceed responsiveness of the mechanical system and take in consideration velocity loop gain, if not it might cause vibration, mechanical noise and overtravel.</p> <p>As velocity loop gain is based on position loop gain, please set both values accordingly.</p> <p>Recommended range: $1.2 \leq Pr1.00/Pr1.01 \leq 1.8$</p>								

Pr1.01	Label	1 st velocity loop gain			Mode	P	V	T
	Range	1~32767	Unit	0.1Hz	Default	180	Index	2101h
	Activation	Immediate						
<p>To determine the responsiveness of the velocity loop. If inertia ratio of Pr0.04 is uniform with actual inertia ratio, velocity loop responsiveness = Pr1.01.</p> <p>To increase position loop gain and improve responsiveness of the whole system, velocity loop gain must be set at higher value. Please notice that if the velocity loop gain is too high, it might cause vibration.</p>								

Pr1.02	Label	1 st Integral Time Constant of Velocity Loop			Mode	P	V	T
	Range	1~10000	Unit	0.1ms	Default	310	Index	2102h
	Activation	Immediate						

If auto gain adjusting function is not enabled, Pr1.02 is activated.
 The lower the set value, the closer the lag error at stop to 0 but might cause vibration. If the value set is overly large, overshoot, delay of positioning time duration and lowered responsiveness might occur.
 Set 10000 to deactivate Pr1.02.
 Recommended range: $50000 \leq PA1.01 \times PA1.02 \leq 150000$

For example: Velocity loop gain Pr1.01=500(0.1Hz), which is 50Hz. Integral time constant of velocity loop should be $100(0.1ms) \leq Pr1.02 \leq 300(0.1ms)$

Pr1.03	Label	1 st velocity detection filter			Mode	P	V	T
	Range	0~10000	Unit	—	Default	15	Index	2103h
	Activation	Immediate						

This filter is a low pass filter. It blocks high frequencies which cause system instability from velocity feedback data. The higher the set value, lower frequencies will be blocked and velocity responsiveness will also be lowered. Pr1.03 needs to match velocity loop gain. Please refer to the following table.

Set Value	Velocity Detection Filter Cut-off Frequency(Hz)	Set Value	Velocity Detection Filter Cut-off Frequency(Hz)
0	2500	16	750
1	2250	17	700
2	2100	18	650
3	2000	19	600
4	1800	20	550
5	1600	21	500

11	1000	27	200
12	950	28	175
13	900	29	150
14	850	30	125
15	800	31	100

Pr1.04	Label	1 st Torque Filter Time Constant			Mode	P	V	T
	Range	0~2500	Unit	0.01ms	Default	126	Index	2104h
	Activation	Immediate						
<p>To set torque command low-pass filter, add a filter delay time constant to torque command and filter out the high frequencies in the command.</p> <p>Often used to reduce or eliminate some noise or vibration during motor operation, but it will reduce the responsiveness of current loop, resulting in undermining velocity loop and position loop control. Pr1.04 needs to match velocity loop gain.</p> <p>Recommended range: $1,000,000/(2\pi \times \text{Pr1.04}) \geq \text{Pr1.01} \times 4$</p> <p>For example: Velocity loop gain Pr1.01=180(0.1Hz) which is 18Hz. Time constant of torque filter should be $\text{Pr1.01} \leq 221(0.01\text{ms})$</p> <p>If mechanical vibration is due to servo driver, adjusting Pr1.04 might eliminate the vibration. The smaller the value, the better the responsiveness but also subjected to machine conditions. If the value is too large, it might lower the responsiveness of current loop.</p> <p>With higher Pr1.01 value settings and no resonance, reduce Pr1.04 value; With lower Pr1.01 value settings, increase Pr1.04 value to lower motor noise.</p>

	Activation	Immediate						
<p>Set velocity feed forward low pass filter to eliminate high or abnormal frequencies in velocity feed forward command. Often used when position command with low resolution or high electronic gear ratio to smoothen velocity feed forward.</p> <p>Position deviation under constant velocity can be lowered with higher velocity feed forward gain. Please to refer to the equation below.</p> $\text{Position deviation[Uint]} = \frac{\text{Set velocity} \left[\frac{\text{Unit}}{\text{s}} \right]}{\text{Position loop gain[Hz]} } \times \frac{100 - \text{Velocity feed forward gain}[\%]}{100}$								

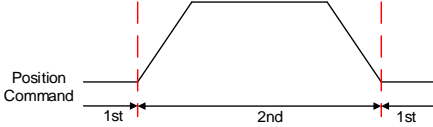

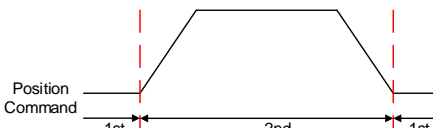

Pr1.12	Label	Torque feed forward gain			Mode	P	V	
	Range	0~1000	Unit	0.1%	Default	0	Index	2112h
	Activation	Immediate						
Before using torque feed forward, please set correct inertia ratio. By increasing torque feed forward gain, position deviation on constant acceleration/deceleration can be reduced to close to 0. Under ideal condition and trapezoidal speed profile, position deviation of the whole motion can be reduced to close to 0. In reality, perturbation torque will always exist, hence position deviation can never be 0.								

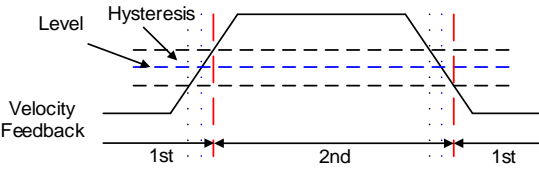

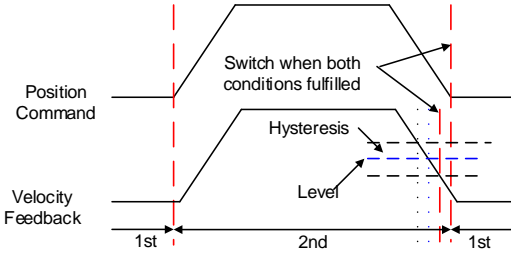

Pr1.13	Label	Torque feed forward filter time constant			Mode	P	V

1. Do not apply more than ±10 V to analog velocity command (SPR).
2. While in velocity control mode in combination with driver external position loop, position gain of the driver will have changes. Vibration might occur if Pr3.02 is set too large.

Pr3.13	Label	Deceleration time settings		Mode	V			
	Range	0~10000	Unit	ms/ (1000RPM)	Default	0	Index	2313h
	Activation	Immediate						

Set max acceleration/deceleration for velocity command.

If target velocity = x [rpm], max acceleration = a [unit: rpm/ms], acceleration time = t [ms]

$$\text{Pr3.12} = 1000/a$$

$$\text{Pr3.13} = 1000/a$$

$$a = x/t$$

For example: If motor is to achieve 1500rpm in 30s, $a=1500/30=50\text{rpm/ms}$

$\text{Pr3.12} = 1000/a = 20$. Hence when $\text{Pr3.12} = 20$, motor can achieve 1500rpm in 30s.

Usually used when there is rapid acceleration or trapezoidal wave velocity command due to many different internal speed segments under velocity control mode which causes instable while motor in motion.

Under velocity control mode, 6083 and 6084 is limited by Pr3.12 and Pr3.13 correspondingly.
